# A Tipping Point of Evaluation on Fragility Effected by Climate Change in China

Huanyu Dong, Hebao Zhang, Wenshang Ji  
College of Qianhu, Nanchang University, Nanchang, 330031, China

**Abstract:** Climate changes has made great influences on instability. It is of vital importance to establish an efficient evaluation system, which meet the following requirements. Figure out when and how climate change force a country become more fragile. Based on the principles of mode and average, we identify the tipping point of 15 factors separately. We define the average as tipping point 1 of transforming from stable to vulnerable, mode as tipping point 2 that turning vulnerable to fragile. If the sum of all the representative numbers is over 22, the country is in fragile status. Then we utilize optimized ANN-Markov model to predict the development trend of China, which proves that it will not fall into fragility in future years.

**Keywords:** ANN Markov chains Fragility

## 1. Introduction

Climate change has been widely regarded as a driver of change in shaping the future of most areas and at scales ranging from individual to the global [1]. Climate change amplifies the negative effects on the areas, which suffer from common environmental problems. The negative issues increase likelihood on climate shocks. Those areas in long run can fall into the degree to which an exposure unit is susceptible to harm due to exposure, to a perturbation or stress, in conjunction with its ability to cope, or fundamentally adapt [2], which is called the fragile state. Thus it is crucial to assess country vulnerability, which can reflect the general process of social ecosystems under climate change [3]

## 2. A Tipping Point

The condition of any country cannot stay the same in the development process. It is essential to figure out the exact tipping point to prevent from falling into the fragile state. We define the tipping point by considering the vulnerable status of the 15 indicators. We obey the principle of mode and average. The average of data set given by Fund for Peace is set as turning point 1 of transform from table to vulnerable status. The mode of data set represents the turning point 2 that turning the vulnerable to fragile status.

**Table 1. The Turning Point of 15 Factors based on Fragility**

	Security Apparatus	Factionalized Elites	Group Grievance	Uneven Economic	Economic Inequality	Human Flight and Brain Drain	State Legitimacy	Public Services
Turning point 1	5.7	6.5	6.2	5.7	5.9	5.7	6.1	5.5
Turning point 2	7.2	8.2	7.8	7	7.6	7.5	8.2	7.9
	Human Rights	Demographic Pressures	Refugees and IDPs	External Intervention	Precipitation	Temperature	Natural disaster	
Turning point 1	5.8	5.8	5.3	5.8	5.8	5.2	5.1	
Turning point 2	7.8	8.1	7.3	7.6	7.7	7.4	7.6	

We value the diverse number in different weights, which is shown as follows.

$$\begin{cases} number \leq tippingpoint1 & weight = 0 \\ tippingpoint1 < number < tippingpoint2 & weight = 1 \\ number \geq tippingpoint2 & weight = 2 \end{cases}$$

If the sum of all the representative numbers is over 22 points, the country is probably in fragile condition. The less number means the more stable condition.

## 3. Evaluate the State of China

The complex indicator of China from 2006 to 2015 is shown in table 2. We conclude the fragility of China is under 22, which means China has been a stable but quite vulnerable status for a decade.

Table 2. The Complex Index in China

Year	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
Complex index	16	15	15	17	17	14	13	15	14	13

### 4. Evaluate the State of China

The prediction on when a country may reach the tipping point is based on the ANN with additional momentum optimized by adaptive variable step model. We set previous and the other separately as the training and test data

set. It is obvious that China will not reach the tipping point in the future. However, there is huge gap between expected and predicted results. To deal with this, we combine the advantages of ANN and Markov chain.

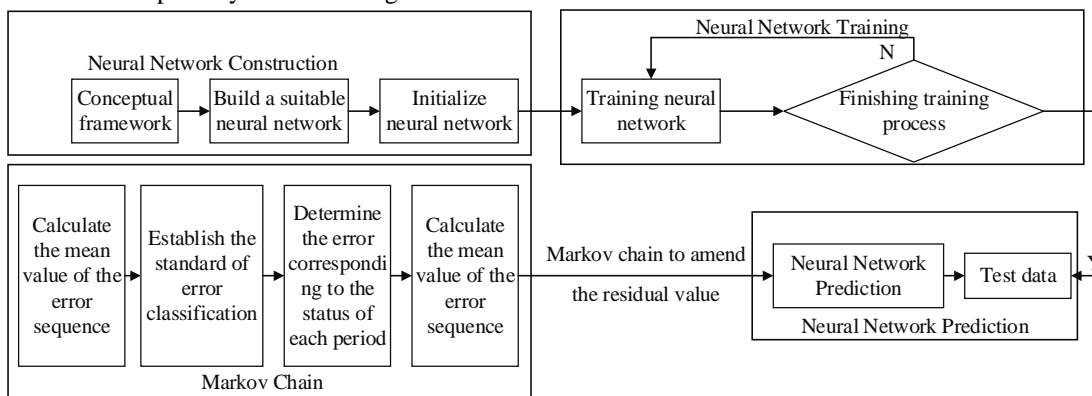

Figure 1. The Flowchart of Optimized ANN-Markov Model

To reflect the effect of optimization model clearly, we compare the relative value between the ANN and improved ANN-Markov Chains model. The relative error

has largely decreased, identifies the proposed ANN-Markov Chains has well performance on diminishing the error.

Table 3. The Comparison of Relative Error between ANN and ANN-Markov Chai

Year	The complex index	ANN		Markov Chains	
		predicted value	relative error	modified value	relative error
2006	82.5	71.2	0.14	80.8	0.02
2007	81.2	68.6	0.16	80.1	0.01
2008	80.3	67.8	0.16	78.3	0.02
2009	84.6	68.7	0.19	81.7	0.03
2010	83.0	68.5	0.17	80.5	0.03

### 5. The Effects of Climate Change on Fragility in China

Figure 2 intuitively reflects the impact of climate change on fragility in China. The darker color represents a more fragile state. There was a slight impact of climate changes on vulnerability in the western China from 2006-2015. But the fragility of south area was deeply influ-

enced by the climate change. Those western area due to its location can prevent themselves from being influenced by extreme disasters. North area is the most stable region of China.

Overall, those area nearby the ocean are the most likely to be influenced by climate change, which has the closest connection with fragility.

Figure 2. The Predictive Trend of Vulnerability in China from 2006 to 2017

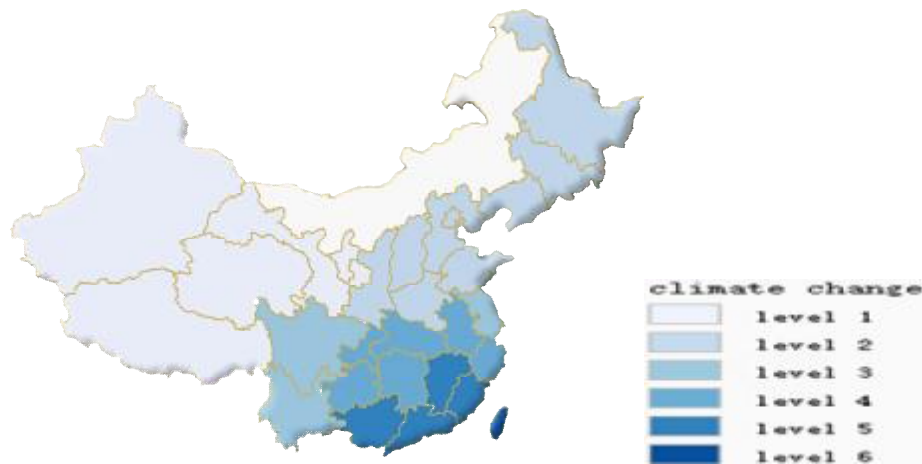

Figure 3. The Influence of Climate Changes on Fragility in China
